1-collections

September 4, 2019

1 Python review: Basic collections of values

This notebook continues the review of Python basics. The focus here is on basic collections: tuples, dictionaries, and sets.

Exercise 0 (`minmax_test`: 1 point). Complete the function `minmax(L)`, which takes a list `L` and returns a pair---that is, 2-element Python tuple, or "2-tuple"---whose first element is the minimum value in the list and whose second element is the maximum. For instance:

```
  minmax([8, 7, 2, 5, 1]) == (1, 8)
```

```
In [1]: def minmax(L):
            assert hasattr(L, "__iter__")
            ###
            ### YOUR CODE HERE
            ###
            return (min(L),max(L))
```

```
In [2]: # `minmax_test`: Test cell

        L = [8, 7, 2, 5, 1]
        mmL = minmax(L)
        mmL_true = (1, 8)
        print("minmax({}) -> {} [True: {}]".format(L, mmL, mmL_true))
        assert type(mmL) is tuple and mmL == (1, 8)

        from random import sample
        L = sample(range(1000), 10)
        mmL = minmax(L)
        L_s = sorted(L)
        mmL_true = (L_s[0], L_s[-1])
        print("minmax({}) -> {} [True: {}]".format(L, mmL, mmL_true))
        assert mmL == mmL_true

        print("\n(Passed!)")
```

```
minmax([8, 7, 2, 5, 1]) -> (1, 8) [True: (1, 8)]
minmax([115, 26, 347, 957, 841, 993, 18, 231, 29, 270]) -> (18, 993) [True: (18, 993)]
```

```
(Passed!)
```

Exercise 1 (`remove_all_test`: 2 points). Complete the function `remove_all(L, x)` so that, given a list `L` and a target value `x`, it returns a *copy* of the list that excludes *all* occurrences of `x` but preserves the order of the remaining elements. For instance:

```
remove_all([1, 2, 3, 2, 4, 8, 2], 2) == [1, 3, 4, 8]
```

Note. Your implementation should *not* modify the list being passed into `remove_all`.

```
In [3]: def remove_all(L, x):
            assert type(L) is list and x is not None
            ###
            ### YOUR CODE HERE
            ###
            k=list()
            for i in L:
                if i != x:
                    k.append(i)
            return k
```

```
In [4]: # `remove_all_test`: Test cell
        def test_it(L, x, L_ans):
            print("Testing `remove_all({}, {})`...".format(L, x))
            print("\tTrue solution: {}".format(L_ans))
            L_copy = L.copy()
            L_rem = remove_all(L_copy, x)
            print("\tYour computed solution: {}".format(L_rem))
            assert L_copy == L, "Your code appears to modify the input list."
            assert L_rem == L_ans, "The returned list is incorrect."

        # Test 1: Example
        test_it([1, 2, 3, 2, 4, 8, 2], 2, [1, 3, 4, 8])

        # Test 2: Random list
        from random import randint
        target = randint(0, 9)
        L_input = []
        L_ans = []
        for _ in range(20):
            v = randint(0, 9)
            L_input.append(v)
            if v != target:
                L_ans.append(v)
        test_it(L_input, target, L_ans)

        print("\n(Passed!)")
```

```
Testing `remove_all([1, 2, 3, 2, 4, 8, 2], 2)`...
        True solution: [1, 3, 4, 8]
        Your computed solution: [1, 3, 4, 8]
Testing `remove_all([2, 9, 8, 6, 0, 8, 9, 6, 5, 4, 3, 9, 2, 0, 3, 3, 4, 8, 8, 7], 4)`...
        True solution: [2, 9, 8, 6, 0, 8, 9, 6, 5, 3, 9, 2, 0, 3, 3, 8, 8, 7]
        Your computed solution: [2, 9, 8, 6, 0, 8, 9, 6, 5, 3, 9, 2, 0, 3, 3, 8, 8, 7]

(Passed!)
```

Exercise 2 (`compress_vector_test`: 2 points). Suppose you are given a vector, `x`, containing real values that are mostly zero. For instance:

```
x = [0.0, 0.87, 0.0, 0.0, 0.0, 0.32, 0.46, 0.0, 0.0, 0.10, 0.0, 0.0]
```

Complete the function, `compress_vector(x)`, so that returns a dictionary `d` with two keys, `d['inds']` and `d['vals']`, which are lists that indicate the position and value of all the *non-zero* entries of `x`. For the previous example,

```
d['inds'] = [1, 5, 6, 9]
d['vals'] = [0.87, 0.32, 0.46, 0.10]
```

Note 1. Your implementation must *not* modify the input vector `x`.

Note 2. If `x` contains only zero entries, `d['inds']` and `d['vals']` should be empty lists.

```
In [5]: def compress_vector(x):
            assert type(x) is list
            d = {'inds': [], 'vals': []}
            ###
            ### YOUR CODE HERE
            ###
            for i in range(0,len(x)):
                if x[i] != 0.0:
                    d['inds'].append(i)
                    d['vals'].append(x[i])
            return d
```

```
In [6]: # `compress_vector_test`: Test cell
        def check_compress_vector(x_orig):
            print("Testing `compress_vector(x={})`:".format(x_orig))
            x = x_orig.copy()
            nz = x.count(0.0)
            print("\t`x` has {} zero entries.".format(nz))
            d = compress_vector(x)
            print("\tx (after call): {}".format(x))
            print("\td: {}".format(d))
            assert x == x_orig, "Your implementation appears to modify the input."
```

```
        assert type(d) is dict, "Output type is not `dict` (a dictionary)."
        assert 'inds' in d and type(d['inds']) is list, "Output key, 'inds', does not have
        assert 'vals' in d and type(d['vals']) is list, "Output key, 'vals', does not have
        assert len(d['inds']) == len(d['vals']), "`d['inds']` and `d['vals']` are lists of
        for i, v in zip(d['inds'], d['vals']):
            assert x[i] == v, "x[{}] == {} instead of {}".format(i, x[i], v)
        assert nz + len(d['vals']) == len(x), "Output may be missing values."
        assert len(d.keys()) == 2, "Output may have keys other than 'inds' and 'vals'."

    # Test 1: Example
    x = [0.0, 0.87, 0.0, 0.0, 0.0, 0.32, 0.46, 0.0, 0.0, 0.10, 0.0, 0.0]
    check_compress_vector(x)

    # Test 2: Random sparse vectors
    from random import random
    for _ in range(3):
        print("")
        x = []
        for _ in range(20):
            if random() <= 0.8: # Make about 10% of entries zero
                v = 0.0
            else:
                v = float("{:.2f}".format(random()))
            x.append(v)
        check_compress_vector(x)

    # Test 3: Empty vector
    x = [0.0] * 10
    check_compress_vector(x)

    print("\n(Passed!)")

Testing `compress_vector(x=[0.0, 0.87, 0.0, 0.0, 0.0, 0.32, 0.46, 0.0, 0.0, 0.1, 0.0, 0.0])`:
    `x` has 8 zero entries.
    x (after call): [0.0, 0.87, 0.0, 0.0, 0.0, 0.32, 0.46, 0.0, 0.0, 0.1, 0.0, 0.0]
    d: {'inds': [1, 5, 6, 9], 'vals': [0.87, 0.32, 0.46, 0.1]}

Testing `compress_vector(x=[0.0, 0.53, 0.91, 0.75, 0.0, 0.0, 0.0, 0.0, 0.0, 0.12, 0.03, 0.25, 0
    `x` has 13 zero entries.
    x (after call): [0.0, 0.53, 0.91, 0.75, 0.0, 0.0, 0.0, 0.0, 0.0, 0.12, 0.03, 0.25, 0.0
    d: {'inds': [1, 2, 3, 9, 10, 11, 19], 'vals': [0.53, 0.91, 0.75, 0.12, 0.03, 0.25, 0.68

Testing `compress_vector(x=[0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.74, 0.0, 0.38, 0.0, 0.0, 0.0, 0.0,
    `x` has 17 zero entries.
    x (after call): [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.74, 0.0, 0.38, 0.0, 0.0, 0.0, 0.0, 0.0
    d: {'inds': [6, 8, 18], 'vals': [0.74, 0.38, 0.08]}

Testing `compress_vector(x=[0.95, 0.0, 0.0, 0.0, 0.51, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0,
```

```
        `x` has 15 zero entries.
        x (after call): [0.95, 0.0, 0.0, 0.0, 0.51, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.6
        d: {'inds': [0, 4, 13, 16, 19], 'vals': [0.95, 0.51, 0.61, 0.24, 0.52]}
Testing `compress_vector(x=[0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0])`:
        `x` has 10 zero entries.
        x (after call): [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0]
        d: {'inds': [], 'vals': []}

(Passed!)
```

Repeated indices. Consider the compressed vector data structure, `d`, in the preceding exercise, which stores a list of indices (`d['inds']`) and a list of values (`d['vals']`).

Suppose we allow duplicate indices, possibly with different values. For example:

```
d['inds'] == [0,   3,   7,   3,   3,   5, 1]
d['vals'] == [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0]
```

In this case, the index 3 appears three times. (Also note that the indices `d['ind']` need not appear in sorted order.)

Let's adopt the convention that when there are repeated indices, the "true" value there is the *sum* of the individual values. In other words, the true vector corresponding to this example of `d` would be:

```
# ind:  0    1    2    3*    4    5    6    7
x == [1.0, 7.0, 0.0, 11.0, 0.0, 6.0, 0.0, 3.0]
```

Exercise 3 (`decompress_vector_test`: 2 points). Complete the function `decompress_vector(d)` that takes a compressed vector `d`, which is a dictionary with keys for the indices (`inds`) and values (`vals`), and returns the corresponding full vector. For any repeated index, the values should be summed.

The function should accept an *optional* parameter, `n`, that specifies the length of the full vector. You may assume this length is at least `max(d['inds'])+1`.

```
In [7]: def decompress_vector(d, n=None):
            # Checks the input
            assert type(d) is dict and 'inds' in d and 'vals' in d, "Not a dictionary or missi
            assert type(d['inds']) is list and type(d['vals']) is list, "Not a list"
            assert len(d['inds']) == len(d['vals']), "Length mismatch"

            # Determine length of the full vector
            i_max = max(d['inds']) if d['inds'] else -1
            if n is None:
                n = i_max+1
            else:
                assert n > i_max, "Bad value for full vector length"

            ###
```

```
    ### YOUR CODE HERE
    ###
    l=[]
    for i in range(0,n):
        l.append(0)

    if len(d['inds']) == 0:
        return l

    for i in range(0,len(d['inds'])):
        if len(d['vals']) > i:
            l[d['inds'][i]] += d['vals'][i]
    return l

#d: {'inds': [3, 5, 3, 5, 3, 3, 5], 'vals': [0.96, 0.15, 0.18, 0.68, 0.52, 0.3, 0.95]}
#decompress_vector(d,10)
```

In [8]:
```
# `decompress_vector_test`: Test cell
def check_decompress_vector(d_orig, x_true):
    print("Testing `decompress_vector(d, n)`:")
    print("\tx_true: {}".format(x_true))
    print("\td: {}".format(d_orig))
    d = d_orig.copy()

        d: {'inds': [1, 1, 1, 0], 'vals': [0.74, 0.23, 0.96, 0.29]}
        n: 10
        => x[:10]: [0.29, 1.93, 0, 0, 0, 0, 0, 0, 0, 0]
```

```
Testing `decompress_vector(d, n)`:
        x_true: [0.0, 0.0, 0.0, 0.0, 2.29, 0.0, 0.81, 2.19, 0.0, 0.0]
        d: {'inds': [7, 6, 4, 7, 4, 4, 7, 7, 6], 'vals': [0.41, 0.04, 0.82, 0.75, 0.5, 0.97, 0
        n: 10
        => x[:10]: [0, 0, 0, 0, 2.29, 0, 0.81, 2.19, 0, 0]

Testing `decompress_vector(d, n)`:
        x_true: [0.0, 0.0, 0.0, 0.16, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0]
        d: {'inds': [3, 3], 'vals': [0.09, 0.07]}
        n: 10
        => x[:10]: [0, 0, 0, 0.16, 0, 0, 0, 0, 0, 0]

Testing `decompress_vector(d, n)`:
        x_true: [0.0, 0.0, 0.0, 0.0, 0.0]
        d: {'inds': [], 'vals': []}
        n: 5
        => x[:5]: [0, 0, 0, 0, 0]

(Passed!)
```

Exercise 4 (`find_common_inds_test`: 1 point). Suppose you are given two compressed vectors, `d1` and `d2`, each represented as described above and possibly with repeated indices. Complete the function `find_common_inds(d1, d2)` so that it returns a list of the indices they have in common.

For instance, suppose:

```
d1 == {'inds': [9, 9, 1, 9, 8, 1], 'vals': [0.28, 0.84, 0.71, 0.03, 0.04, 0.75]}
d2 == {'inds': [0, 9, 9, 1, 3, 3, 9], 'vals': [0.26, 0.06, 0.46, 0.58, 0.42, 0.21, 0.53, 0
```

Then:

```
find_common_inds(d1, d2) == [1, 9]
```

Note 1. The returned list must not have duplicate indices, even if the inputs do. In the example, the index 9 is repeated in both `d1` and `d2`, but the output includes just one 9.

Note 2. In the returned list, the order of indices does not matter. For instance, the example shows `[1, 9]` but `[9, 1]` would also be valid.

```
In [9]: def find_common_inds(d1, d2):
            assert type(d1) is dict and 'inds' in d1 and 'vals' in d1
